centrifugal compressors have multiple impellers stacked together and connected by flow passages. Although centrifugal compressors are sometimes called radial compressors, most of the flow exiting a centrifugal impeller does not travel in a radial direction. Rather, the flow travels to a large extent in a tangential direction.

The return bend is found in multistage centrifugal compressors and is a stationary component which redirects the gas from a radially outward flow in the diffuser to a radially inward flow into the return channel which contains the next stage's guide vanes (as previously mentioned, these vanes help to straighten and smooth the gas flow preceding the downstream impeller).

Centrifugal compressors run at speeds between 20,000 and 30,000 RPM. They are typically engine or turbine driven. Turbines are commonly used due to high rotating speeds. Centrifugal compressors are used in pipeline booster service where high volume and low compression ratios exist. They are also used in very high flow rate gas lift service.

### **Centrifugal Compressors - A Basic Guide - Knovel**

Centrifugal compressors, sometimes called radial compressors, are a sub-class of dynamic axisymmetric work-absorbing turbomachinery.. They achieve a pressure rise by adding kinetic energy/velocity to a continuous flow of fluid through the rotor or impeller.This kinetic energy is then converted to an increase in potential energy/static pressure by slowing the flow through a diffuser.
